IN THE BLINK OF AN EYE

2ND EDITION
much a putting together as it is a discovery of a path, and that the overwhelming majority of an editor’s time is not spent actually splicing film. The more film there is to work with, of course, the greater the number of pathways that can be considered, and the possibilities compound upon each other and consequently demand more time for evaluation. This is true for any film with a high shooting ratio, but in the particular case of *Apocalypse* the effect was magnified by a sensitive subject matter and a daring and unusual structure, technical innovations at every level, and the obligation felt by all concerned to do the very best work they were capable of. And perhaps most of all by the fact that this was, for Francis, a personal film, despite the large budget and the vast canvas of the subject. Regrettably few films combine such qualities and aspirations.

For every splice in the finished film there were probably fifteen “shadow” splices—splices made, considered, and then undone or lifted from the film. But even allowing for that, the remaining eleven hours and fifty-eight minutes of each working day were spent in activities that, in their various ways, served to clear and illuminate the path ahead of us: screenings, discussions, rewinding, re-screenings, meetings, scheduling, filing trims, note-taking, bookkeeping, and lots of plain deliberative thought. A vast amount of preparation, really, to arrive at the innocuously brief moment of decisive action: the cut—the moment of transition from one shot to the next—something that, appropriately enough, should look almost self-evidently simple and effortless, if it is even noticed at all.

**Why Do Cuts Work?**

Well, the fact is that *Apocalypse Now*, as well as every other theatrical film (except perhaps Hitchcock’s *Rope*), is made up of many different pieces of film joined together into a mosaic of images. The mysterious part of it, though, is that the joining of those pieces—the “cut” in American terminology—actually does seem to work, even though it represents a total and instantaneous displacement of one field of vision with another, a displacement that sometimes also entails a jump forward or backward in time as well as space.

It works; but it could easily have been otherwise, since nothing in our day-to-day experience seems to prepare us for such a thing. Instead, from the moment we get up in the morning until we close our eyes at night, the visual reality we perceive is a continuous

---

3 A film composed of only ten shots, each ten minutes long, invisibly joined together, so that the impression is of a complete lack of editing.

4 I was aware, talking to an Australian audience, of the bias inherent in our respective languages. In the States, film is “cut,” which puts the emphasis on *separation*. In Australia (and in Great Britain), film is “joined,” with the emphasis on *bringing together*. 
stream of linked images: In fact, for millions of years—
tens, hundreds of millions of years—life on Earth has
experienced the world this way. Then suddenly, at the
beginning of the twentieth century, human beings were
confronted with something else—edited film.

Under these circumstances, it wouldn't have been
at all surprising to find that our brains had been “wired”
by evolution and experience to reject film editing. If
that had been the case, then the single-shot movies
of the Lumière Brothers—or films like Hitchcock's
Rope—would have become the standard. For a num-
ber of practical (as well as artistic) reasons, it is good
that it did not.

The truth of the matter is that film is actually be-
ing “cut” twenty-four times a second. Each frame is a
displacement from the previous one—it is just that in
a continuous shot, the space/time displacement from
frame to frame is small enough (twenty milliseconds)
for the audience to see it as motion within a context
rather than as twenty-four different contexts a sec-
ond. On the other hand, when the visual displace-
ment is great enough (as at the moment of the cut),
we are forced to re-evaluate the new image as a dif-
ferent context: miraculously, most of the time we have
no problem in doing this.

What we do seem to have difficulty accepting are
the kind of displacements that are neither subtle nor
total: Cutting from a full-figure master shot, for in-
stance, to a slightly tighter shot that frames the actors
from the ankles up. The new shot in this case is dif-
ferent enough to signal that something has changed,
but not different enough to make us re-evaluate its
context: The displacement of the image is neither
motion nor change of context, and the collision of
these two ideas produces a mental jarring—a jump—
that is comparatively disturbing. At any rate, the discovery early in this century that
certain kinds of cutting “worked” led almost immedi-
ately to the discovery that films could be shot discon-
tinuously, which was the cinematic equivalent of the
discovery of flight: In a practical sense, films were no
longer “earthbound” in time and space. If we could
make films only by assembling all the elements si-
multaneously, as in the theater, the range of possible
subjects would be comparatively narrow. Instead,
Discontinuity is King: It is the central fact during the
production phase of filmmaking, and almost all deci-
sions are directly related to it in one way or another—
how to overcome its difficulties and/or how to best
take advantage of its strengths. The other consideration is that even if everything
were available simultaneously, it is just very difficult

---

5 A beehive can apparently be moved two inches each night without
disorienting the bees the next morning. Surprisingly, if it is moved
two miles, the bees also have no problem: They are forced by the
total displacement of their environment to re-orient their sense of
direction, which they can do easily enough. But if the hive is moved
two yards, the bees will become fatally confused. The environment
does not seem different to them, so they do not re-orient themselves,
and as a result, they will not recognize their own hive when they
return from foraging, hovering instead in the empty space where the
hive used to be, while the hive itself sits just two yards away.

6 When Stanley Kubrick was directing The Shining, he wanted to shoot
the film in continuity and to have all sets and actors available all the
time. He took over almost the entire studio at Elstree (London), built
all the sets simultaneously, and they sat there, pre-lit, for however
long it took him to shoot the film. But The Shining remains a special
exception to the general rule of discontinuity.
to shoot long, continuous takes and have all the contributing elements work each time. European filmmakers tend to shoot more complex master shots than the Americans, but even if you are Ingmar Bergman, there’s a limit to what you can handle: Right at the end, some special effect might not work or someone might forget their lines or some lamp might blow a fuse, and now the whole thing has to be done again. The longer the take, of course, the greater the chances of a mistake.

So there is a considerable logistical problem of getting everything together at the same time, and then just as serious a problem in getting it all to “work” every time. The result is that, for practical reasons alone, we don’t follow the pattern of the Lumière Brothers or of Rope.

On the other hand, apart from matters of convenience, discontinuity also allows us to choose the best camera angle for each emotion and story point, which we can edit together for a cumulatively greater impact. If we were limited to a continuous stream of images, this would be difficult, and films would not be as sharp and to the point as they are.  

And yet, beyond even these considerations, cutting is more than just the convenient means by which discontinuity is rendered continuous. It is in and for itself—by the very force of its paradoxical suddenness—a positive influence in the creation of a film. We would want to cut even if discontinuity were not of such great practical value.

So the central fact of all this is that cuts do work. But the question still remains: Why? It is kind of like the bumble-bee, which should not be able to fly, but does.

We will get back to this mystery in a few moments.

---

7 Visual discontinuity— although not in the temporal sense—is the most striking feature of Ancient Egyptian painting. Each part of the human body was represented by its most characteristic and revealing angle: head in profile, shoulders frontal, arms and legs in profile, torso frontal—and then all these different angles were combined in one figure. To us today, with our preference for the unifying laws of perspective, this gives an almost comic “twisted” look to the people of Ancient Egypt—but it may be that in some remote future, our films, with their combination of many different angles (each being the most “revealing” for its particular subject), will look just as comic and twisted.
a chimpanzee film that someone tried to turn it into a human-being film, and it came out being neither.

Or film “Y,” which was an ambitious project that tried to deal with complex, subtle issues, but the studio got to it and ordered additional material to be shot, filled with action and sex, and, as a result, a great potential was reduced to something less, neither human nor chimp.

Most with the least

You can never judge the quality of a sound mix simply by counting the number of tracks it took to produce it. Terrible mixes have been produced from a hundred tracks. By the same token, wonderful mixes have been made from only three tracks. It depends on the initial choices that were made, the quality of the sounds, and how capable the blend of those sounds was of exciting emotions hidden in the hearts of the audience. The underlying principle: Always try to do the most with the least—with the emphasis on try. You may not always succeed, but attempt to produce the greatest effect in the viewer’s mind by the least number of things on screen. Why? Because you want to do only what is necessary to engage the imagination of the audience—suggestion is always more effective than exposition. Past a certain point, the more effort you put into wealth of detail, the more you encourage the audience to become spectators rather than participants. The same principle applies to all the various crafts of filmmaking: acting, art direction, photography, music, costume, etc.

And, of course, it applies to editing as well. You would never say that a certain film was well-edited
because it had more cuts in it. Frequently, it takes more work and discernment to decide where not to cut—don’t feel you have to cut just because you are being paid to. You are being paid to make decisions, and as far as whether to cut or not, the editor is actually making twenty-four decisions a second: “No. No. No. No. No. No. No. No. No. Yes!”

An overactive editor, who changes shots too frequently, is like a tour guide who can’t stop pointing things out: “And up there we have the Sistine Ceiling, and over here we have the Mona Lisa, and, by the way, look at these floor tiles . . .” If you are on a tour, you do want the guide to point things out for you, of course, but some of the time you just want to walk around and see what you see. If the guide—that is to say, the editor—doesn’t have the confidence to let people themselves occasionally choose what they want to look at, or to leave things to their imagination, then he is pursuing a goal (complete control) that in the end is self-defeating. People will eventually feel constrained and then resentful from the constant pressure of his hand on the backs of their necks.

Well, if what I’m saying is to do more with less, then is there any way to say how much less? Is it possible to take this right to its absurd logical conclusion and say, “Don’t cut at all?” Now we’ve come back to our first problem: Film is cut for practical reasons and film is cut because cutting—that sudden disruption of reality—can be an effective tool in itself. So, if the goal is as few cuts as possible, when you have to make a cut, what is it that makes it a good one?

The Rule of Six

The first thing discussed in film-school editing classes is what I’m going to call three-dimensional continuity: In shot A, a man opens a door, walks halfway across the room, and then the film cuts to the next shot, B, picking him up at that same halfway point and continuing with him the rest of the way across the room, where he sits down at his desk, or something.

For many years, particularly in the early years of sound film, that was the rule. You struggled to preserve continuity of three-dimensional space, and it was seen as a failure of rigor or skill to violate it.9 Jumping people around in space was just not done, except, perhaps, in extreme circumstances—fights or earthquakes—where there was a lot of violent action going on.

I actually place this three-dimensional continuity at the bottom of a list of six criteria for what makes a

---

9 The problem with this thinking can be seen in any multi-camera situation-comedy on television. Because the cameras are filming simultaneously, the actors are necessarily always “correct” as far as their spatial continuity and relation to each other is concerned, but that absolutely does not prevent bad cuts from being made all the time.
memory of a memory of a memory of a memory—and it was perhaps one too many. I suggested eliminating of one scene that occupied a unique time-frame in the film’s structure (one that was never reprised), and we decided to remove this, since it meant that the scenes that were left would consequently sort themselves into a more graspable sequence. As I was undoing the splices (and they made a little screech as they came apart, almost as if they were crying out in pain), Zinnemann looked thoughtfully at what was happening and observed in an almost offhand way, “You know, when I first read this scene in the script, I knew that I could do this film.”

I hesitated briefly, looked at him, and then continued undoing the splices. But my heart was in my throat because at that stage in the process you do not know; you can only have faith that what you are doing is the right thing. Were we mistakenly cutting out the heart of the film, or were we snipping off the umbilical cord?

In retrospect, I believe it was the umbilical cord and that we were right to remove it: The scene did have an essential function at one point, which was to connect Fred Zinnemann to the project, but once that connection had been made and Zinnemann’s sensibility had flowed through that scene into all the other scenes in the film, it could finally be removed without any harm.

But things like that do give you pause.

Don’t Worry, It’s Only a Movie

Earlier I asked the question, “Why do cuts work?” We know that they do. And yet it is still surprising when you think about it because of the violence of what is actually taking place: At the instant of the cut, there is a total and instantaneous discontinuity of the field of vision.

I recall once coming back to the editing room after a few weeks in the mixing theater (where all movements are smooth and incremental) and being appalled at the brutality of the process of cutting. The “patient” is pinned to the slab and: Whack! Either/Or! This not That! In or Out! We chop up the poor film in a miniature guillotine and then stick the dismembered pieces together like Dr. Frankenstein’s monster. The difference (the miraculous difference) is that out of this apparent butchery our creation can sometimes gain not only a life but a soul as well. It is all the more amazing because the instantaneous displacement achieved by the cut is not anything that we experience in ordinary life.
We are accustomed to such things, of course, in music (Beethoven was the innovator and master of this) as well as in our own thoughts—the way one realization will suddenly overwhelm everything else, to be, in turn, replaced by yet another. But in the dramatic arts—theater, ballet, opera—there didn't seem to be any way to achieve total instantaneous displacement: stage machinery can only move so fast, after all. So why do cuts work? Do they have some hidden foundation in our own experience, or are they an invention that suits the convenience of filmmakers and people have just, somehow, become used to them?

Well, although “day-to-day” reality appears to be continuous, there is that other world in which we spend perhaps a third of our lives: the “night-to-night” reality of dreams. And the images in dreams are much more fragmented, intersecting in much stranger and more abrupt ways than the images of waking reality—ways that approximate, at least, the interaction produced by cutting.

Perhaps the explanation is as simple as that: We accept the cut because it resembles the way images are juxtaposed in our dreams. In fact, the abruptness of the cut may be one of the key determinants in actually producing the similarity between films and dreams. In the darkness of the theater, we say to ourselves, in effect, “This looks like reality, but it cannot be reality because it is so visually discontinuous; therefore, it must be a dream.”

(Along those lines, it is revealing that the words a parent uses to comfort a child frightened by a nightmare—“Don't worry, darling, it's only a dream”—are almost the same words used to comfort a child frightened by a film—“Don't worry, darling, it's only a movie.” Frightening dreams and films have a similar power to overwhelm the defenses that are otherwise effective against equally frightening books, paintings, music. For instance, it is hard to imagine this phrase: “Don't worry, darling, it's only a painting.”)

The problem with all this is that the comparison of films and dreams is interesting, probably true, but relatively barren of practical fruits: We still know so little about the nature of dreams that the observation comes to a stop once it has been made.

Something to consider, though, is the possibility that there may be a part of our waking reality where we actually do experience something like cuts, and where daylight images are somehow brought in closer, more discontinuous, juxtaposition than might otherwise seem to be the case.

I began to get a glimmer of this on my first picture-editing job—The Conversation (1974)—when I kept finding that Gene Hackman (Harry Caul in the film) would blink very close to the point where I had decided to cut. It was interesting, but I didn't know what to make of it.

Then, one morning after I had been working all night, I went out to get some breakfast and happened to walk past the window of a Christian Science Reading Room, where the front page of the Monitor featured an interview with John Huston. I stopped to read it, and one thing struck me forcefully because it related exactly to this question of the blink:
To me, the perfect film is as though it were unwinding behind your eyes, and your eyes were projecting it themselves, so that you were seeing what you wished to see. Film is like thought. It's the closest to thought process of any art.

Look at that lamp across the room. Now look back at me. Look back at that lamp. Now look back at me again. Do you see what you did? You blinked. Those are cuts. After the first look, you know that there's no reason to pan continuously from me to the lamp because you know what's in between. Your mind cut the scene. First you behold the lamp. Cut. Then you behold me.12

What Huston asks us to consider is a physiological mechanism—the blink—that interrupts the apparent visual continuity of our perceptions: My head may move smoothly from one side of the room to the other, but, in fact, I am cutting the flow of visual images into significant bits, the better to juxtapose and compare those bits—“lamp” and “face” in Huston’s example—without irrelevant information getting in the way.

Of course there are limits to the kind of juxtapositions I can make this way—I can’t jump forward or backward in time and space (that is the prerogative of dreams and films).13 But even so, the visual displacements available to me just by turning my head (from the Grand Canyon in front of me to the forest behind me, or even from one side of this room to the other) are sometimes quite great.

13 But see footnote #16.

After I read that article, I started observing people, watching when they blinked, and I began to discover something much different than what they tell you in high-school biology, which is that the blink is simply a means to moisten the surface of the eye. If that’s all it is, then for each environment and each individual there would be a purely mechanical, predictable interval between blinks depending on the humidity, temperature, wind speed, etc. You would only blink when your eye began to get too dry, and that would be a constant number of seconds for each environment. This is clearly not the case: People will sometimes keep their eyes open for minutes at a time—at other times they will blink repeatedly—with many variations in between. The question then is, “What is causing them to blink?”

On the one hand, I’m sure you’ve all been confronted by someone who was so angry that he didn’t blink at all: This is a person, I believe, in the grip of a single thought that he holds (and that holds him), inhibiting the urge and need to blink.14 And then there is the opposite kind of anger that causes someone to blink every second or so: This time, the person is being assailed simultaneously by many conflicting emotions and thoughts, and is desperately (but unconsciously) using those blinks to try to separate these thoughts, sort things out, and regain some kind of control.

14 There is that telling phrase from classic cowboy (and now diplomatic) stand-offs: “he blinked.” The loser in this mental game of chicken could not hold fast to his single position and instead allowed some other thought to intrude at the critical moment. The blink signals the moment he relinquished his primary thought.
IN THE BLINK OF AN EYE

So it seems to me that our rate of blinking is somehow geared more to our emotional state and to the nature and frequency of our thoughts than to the atmospheric environment we happen to find ourselves in. Even if there is no head movement (as there was in Huston's example), the blink is either something that helps an internal separation of thought to take place, or it is an involuntary reflex accompanying the mental separation that is taking place anyway.15

And not only is the rate of blinking significant, but so is the actual instant of the blink itself. Start a conversation with somebody and watch when they blink. I believe you will find that your listener will blink at the precise moment he or she "gets" the idea of what you are saying, not an instant earlier or later. Why would this be? Well, speech is full of unobserved grace notes and elaborations—the conversational equivalents of "Dear Sir" and "Yours Sincerely"—and the essence of what we have to say is often sandwiched between an introduction and a conclusion. The blink will take place either when the listener realizes our "introduction" is finished and that now we are going to say something significant, or it will happen when he feels we are "winding down" and not going to say anything more significant for the moment.

And that blink will occur where a cut could have happened, had the conversation been filmed. Not a frame earlier or later.

So we entertain an idea, or a linked sequence of ideas, and we blink to separate and punctuate that idea from what follows. Similarly—in film—a shot presents us with an idea, or a sequence of ideas, and the cut is a "blink" that separates and punctuates those ideas.16 At the moment you decide to cut, what you are saying is, in effect, "I am going to bring this idea to an end and start something new." It is important to emphasize that the cut by itself does not create the "blink moment"—the tail does not wag the dog. If the cut is well-placed, however, the more extreme the visual discontinuity—from dark interior to bright exterior, for instance—the more thorough the effect of punctuation will be.

At any rate, I believe "filmic" juxtapositions are taking place in the real world not only when we dream but also when we are awake. And, in fact, I would go so far as to say that these juxtapositions are not accidental mental artifacts but part of the method we use to make sense of the world: We must render visual reality discontinuous, otherwise perceived reality would resemble an almost incomprehensible string of letters without word separation or punctuation. When we sit in the dark theater, then we find edited film a (surprisingly) familiar experience. "More like thought than anything else," in Huston's words.17

15 Dr. John Stern of Washington University in St. Louis has recently (1987) published experimental work in the psycho-physiology of the blink that seems to confirm this.

16 This can occur regardless of how big or small the "idea" happens to be. For instance, the idea could be as simple as "she moves quickly to the left."

17 William Stokoe makes an intriguing comparison between the techniques of film editing and American Sign Language: "In signed language, narrative is no longer linear. Instead, the essence is to cut from a normal view to a close-up to a distant shot to a close-up again, even including flashback and flash-forward scenes, exactly as a movie editor works. Not only is signing arranged more like edited film than like written narration, but also each signer is placed very much as a camera: the field of vision and angle of view are directed but variable." William Stokoe, Language in Four Dimensions, New York Academy of Sciences (1979).
